Scatter-brained approach

Instead of: Global linear registration of brain to atlas, or
 Warping of continuous deformable surfaces,

Mindboggle:

- (1) Breaks each brain image into pieces
- (2) Groups the pieces into combinations
- (3) Matches combinations of pieces across brains
- (4) Labels structural/functional data

Mindboggle

Fully automated: Matlab code (tested on Linux/Unix platforms)

Feature-based vs. intensity-based matching

Robust to reduced and nonuniform image quality

Labels the entire cortex and can transfer anatomical labels to any regions of interest / activated voxels

Does not assume that different brains:

preserve topology

- gyri interrupt sulci
- sulcus sequences may vary

have complete homology

- sulci may be present or absent across brains

Mindboggle

Mindboggle

coregister atlas and subject MRIs

Mindboggle requires:

- (1) a common space for linear coregistration (**MNI152**),
- (2) **Atlas** data (MNI's single-subject Atlas),
- (3) skull-stripped, linearly coregistered, and segmented **Subject** MRI data, and
- (4) **manual labels** for atlas-labeling and independent evaluation.

Mindboggle

extract 3-D sulcus pieces

Thin **segmented** non-white matter to a **skeleton** for each slice (only step in 2-D).

Divide the sulcus skeleton into left and right **hemispheres** by warping a plane to the inter-hemispheric plane.

Combine each 2-D sulcus cross-section with those from adjacent slices, fragment the resulting 3-D pieces along vertical bifurcations, and recluster the pieces into 100s of **3-D sulcus pieces** with a modified k-means algorithm.

Mindboggle

combine and match pieces

Match combinations of subject pieces to each atlas piece, and order the tentative matches by a simple **cost function**:

$$\mathbf{E}_M = \mathbf{w}_N \mathbf{N} + \mathbf{w}_V \mathbf{V} + \mathbf{w}_P \mathbf{P} + \mathbf{w}_O \mathbf{O}$$

$$\left\{ \begin{array}{l} \mathbf{N} = \Delta \text{ number of points} \\ \mathbf{V} = \Delta \text{ number of subvolumes} \\ \mathbf{P} = \Delta \text{ mean position} \\ \mathbf{O} = \text{degree of non-overlap} \end{array} \right.$$

Mindboggle

transform label boundaries

Translate each patch of atlas label boundaries to the matching subject pieces.
(Each patch is defined as the atlas label boundary points nearest to an atlas piece.)

No warping is performed at this stage – only piece-wise linear translation

Mindboggle

warp and interpolate labels

Warp Atlas labels (with a **modified Self-Organizing Map**) to smoothly fill the Atlas label boundaries that have been broken up and transformed to the subject sulcus pieces. **Label unlabeled voxels by the majority label in a new neighborhood.**

From left:

- (1) Atlas labels,
- (2) Atlas labels after deformation to the subject,
- (3) the interpolated result, and
- (4) subject manual labels.

transfer labels to activity data

The resulting labels may be transferred to a coregistered volume of activity data.

In this example, 5 standard tasks elicited BOLD activity in expected regions.

Evaluation of Mindboggle

Evaluation of Mindboggle

Label agreement metric

**Comparison with
Linear
AIR
SPM2
ANIMAL**

Functional mapping tests

Label agreement metric

$$\frac{V_a}{V_i} = \frac{\text{intersecting voxels with the same label}}{\text{intersecting voxels}}$$

Evaluation of Mindboggle

Comparison of label agreements

A nonparametric Friedman's ANOVA test (with Dunn-Sidak critical values) was used to compare the percent label agreements between manual and automated labels obtained by each of the methods. Mindboggle and ANIMAL were found to have mean ranks significantly higher than that obtained by linear registration ($p < 0.05$). When **uninterpolated Mindboggle labels** are tested, its mean rank is significantly greater than that of SPM2 as well.

Evaluation of Mindboggle

Functional mapping tests

Mindboggle labeled activity from 5 subjects undergoing 4 standard tasks that are known to elicit activity in specific regions (Hirsch, 2000). We determined whether Mindboggle's labels included those regions. According to Mindboggle, of the 45 gyri expected to be activated (9 gyri distributed across 4 tasks performed by 5 subjects), 44 were activated, well within expected variance of the subject pool.

Conclusions

Mindboggle is an alternative tool to fully automate cortical anatomical labeling that outperforms other methods such as linear coregistration, AIR, and SPM2 nonlinear registration. Mindboggle performs comparably with ANIMAL, with fewer assumptions. We hope that it will find its place as a useful tool for brain imagers.

Mindboggle: Fully automated

Does not assume that different brains preserve topology or have complete homology

Feature-based vs. intensity-based registration

Robust to reduced and nonuniform image quality

May apply mask to transfer labels to any regions of interest / activated voxels

Label BOLD activity for 5 tasks

(1 of 5 subjects)

Tasks

- T1 = original T1 slices
- A = everything labeled
- M1 = motor hand task
- M2 = motor tongue task
- S = tactile hand task
- L = listening task
- P = picture-naming task

Clinical battery:

Hirsch, J., et. al. 2000.
 An integrated functional magnetic resonance imaging procedure for preoperative mapping of cortical areas associated with tactile, motor, language, and visual functions. *Neurosurgery* 47: 711-721.

Labels

- sFG = superior Frontal Gyrus
- mFG = middle Frontal Gyrus
- iFG = inferior Frontal Gyrus
- sTG = superior Temporal Gyrus
- mTG = middle Temporal Gyrus
- iTG = inferior Temporal Gyrus
- prCG = preCentral Gyrus
- poCG = postCentral Gyrus
- sPL = superior Parietal Lobe
- iPL = inferior Parietal Lobe
- OL = Occipital Lobe
